

Leaders in Women's Health Encourage Health Workers to Receive the COVID-19 Vaccine *Vaccination is the Key to Preventing New Infections*

January 13, 2021 – During the COVID-19 pandemic, public health measures such as physical distancing, masking, hand hygiene, and appropriate personal protective equipment for healthcare personnel have proven critical in minimizing the spread of existing COVID-19 infection. Vaccination is the key to preventing new infections and is an important next step to combatting the COVID-19 pandemic and saving lives.

“Frontline health workers are encouraged to be vaccinated, to learn the safety profile of approved vaccines, and to inspire vaccine confidence among their communities,” said Judette Louis, MD, MPH, President of the Society for Maternal-Fetal Medicine. “In addition to affording significant individual-level protection, keeping healthcare workers safe protects the workforce so we can continue to provide care to those who are sick with COVID-19 or other illnesses. By preventing the COVID-19 infections, vaccination also helps prevent healthcare workers from spreading COVID-19 infection to patients and other healthcare workers.”

Vaccinations Are Safe and Effective

The vaccines that are currently approved for the prevention of COVID-19 (Pfizer and Moderna) in the United States are mRNA vaccines, which help the body create antibodies to fight future infection. The vaccines do not contain live COVID-19 virus. Data suggest that mRNA is rapidly degraded in the body by normal cellular processes in about 10 to 20 days.

The Pfizer vaccine study included 43,448 people who received two doses of the vaccine 21 days apart. The efficacy of preventing COVID-19 after the second dose was 95%.¹ The Moderna vaccine study included 30,350 people who received two doses of the vaccine 28 days apart. The efficacy of preventing COVID-19 after the second dose was 94.1%.² Common side effects of both vaccines include mild to moderate fever, headache, and muscle aches. These side effects suggest that the immune system is working.^{1,2}

“After an explicit, evidence-based review of all available data, the Advisory Committee on Immunization Practices (ACIP) has issued recommendations for use of these vaccines, as both have been demonstrated safe and effective in preventing COVID-19 infection, and thereby increasing community immunity against the virus,” said Cyndy Krening, MS, RN, President of the Association of Women's Health, Obstetric and Neonatal Nurses.

“The Centers for Disease Control and Prevention (CDC) are tracking vaccine side effects through a smartphone-based tool called V-Safe,” said Diana Drake, DNP, WHNP, FAAN, President of the Nurse Practitioners in Women's Health. “Vaccine recipients are encouraged to [register for the no-cost program](#) for personalized health check-ins and to report any side effects.”

The Impact of Vaccinations on Future Fertility, Pregnancy, and Lactation

In the United States, 75% of healthcare workers are women, and the Centers for Disease Control and Prevention (CDC) estimates that 330,000 healthcare workers are pregnant or have recently given birth. The approved vaccines are available to [pregnant and lactating people](#).

“Pregnant people should discuss the benefits and risks of COVID vaccination with their healthcare provider,” said Jennifer Butler, MD, President of the Society of ObGyn Hospitalists. “Frontline health workers are more likely to be exposed to COVID-19 and, if pregnant, more likely to be admitted to the ICU, need advanced life support and a breathing tube, and even die.”

While pregnant people were not allowed to take part in the clinical trials for the COVID-19 vaccines, many healthcare workers who are pregnant or lactating have received the vaccine and have registered for a [COVID-19 vaccine registry](#) so that scientists can better understand the impacts of COVID-19 vaccination on pregnancy.

“There is no data to suggest that vaccination impacts future fertility,” said Hugh Taylor, MD, President of the American Society for Reproductive Medicine. “Because the approved COVID-19 vaccines do not use a live virus, they are not thought to cause an increased risk of infertility, first- or second-trimester loss, stillbirth, or congenital abnormalities.”

Vaccines Should Be Distributed Equitably

ACIP recommended that healthcare personnel and long-term care facility residents be offered COVID-19 vaccination first (Phase 1a).³ Healthcare personnel include all those who come into contact with patients including, but not limited to: transport personnel, environmental services (cleaning and maintenance staff), nutrition service staff, physical and occupational therapists, phlebotomists, pharmacists, technicians, unit secretaries, nurses, nursing assistants, and physicians.

“The vaccine should be offered to individuals in all of these roles in an equitable and transparent manner,” said Cathy Collins-Fulea, CNM, DNP, FACNM, President of the American College of Nurse-Midwives. “Priority should be given to those with the most patient contact and should include trainees.”

“Health care professionals, including obstetrician-gynecologists, have the opportunity to demonstrate to their patients and their communities the value of COVID-19 vaccination by leading by example and receiving the vaccine themselves,” said Eva Chalas, MD, FACOG, FACS, President of the American College of Obstetricians and Gynecologists. “We also have a responsibility to counsel patients, including our pregnant colleagues in the health care workforce, about their risk of severe complications associated with COVID-19 infection, the available evidence regarding the safety of vaccination, and their own individual values and priorities.”
